When a certain proportion exists between steam and water, the evaporation of the water exactly compensates for the condensation of the steam: a proportion which is given by the equation  $x = i, h$  where  $T_1 T_2$  are the initial and final temperatures between which the change is supposed to take place. For a small change at temperature  $T$ , the above formula is very approximately equivalent to  $T x = . 1440$  At 38 lbs. on the square inch, this gives-5 as the value of  $x$ , which at high pressures will be at most-6, and at low pressures at least-45: if a greater change of temperature be considered, the variation in  $x$  will be less, and we may say generally that when a mixture of steam and water in equal proportions by weight expands without gain or loss of heat, the evaporation and condensation approximately balance one another, so that the total change is very small: and further, if water predominates, evaporation takes place, but if steam predominates, condensation. Similar conclusions may be drawn in the case where a mixture of steam and water expands in contact with a metallic plate: the state of things is the same as if the water received the whole amount of heat given out by the cooling plate, and expanded alone without connection with the steam, while the steam condenses as if the plate were not there. When the water forms...
